It’s personal

Changing products
Terminology

**Detergent (surfactant)** - Commonly referred to as soap.

Compounds that possess a cleaning action. They are composed of a hydrophilic and a lipophilic part and can be divided into four groups:

1. anionic
2. cationic
3. amphoteric
4. non-ionic.
Terminology

**Antimicrobial (medicated) soap**

Soap (detergent) containing an antiseptic agent at a concentration sufficient to inactivate microorganisms and/or temporarily suppress their growth.

The detergent activity of such soaps may also dislodge transient microorganisms or other contaminants from the skin to facilitate their subsequent removal by water.
Terminology

**Antiseptic agent**

An antimicrobial substance that inactivates microorganisms or inhibits their growth on living tissues. Examples include:

- Alcohols
- Chlorhexidine gluconate (CHG)
- Iodine
- Chloroxylenol (PCMX)
- Triclosan
- Chlorine derivatives
- Quaternary ammonium compounds
Terminology

Alcohol based hand rub

An alcohol-containing preparation (liquid, gel or foam) designed for application to the hands to reduce the growth of microorganisms. Such preparations may contain one or more types of alcohol with excipients, other active ingredients and humectants.
Physiology of normal skin – protecting the skin barrier
External substances can interact with the skin in three ways:

They can interact with the cells directly; they can penetrate the interstices of the cells; or they can gain entrance through the pilosebaceous and sweat gland orifices.
Causes of occupational dermatoses

Chemical
Mechanical
Physical
Biological.

In one study, approximately 25% of nurses reported symptoms or signs of dermatitis on their hands, and 85% gave a history of skin problems, Larson E, Friedman C, Cohran J, Treston-Aurand J, Green S. Prevalence and correlates of skin damage on the hands of nurses. Heart Lung 1997;26:404-12.
Acid Mantle

Protects from microorganisms, injury, and invasion. Traps water in body.

Sebum protects the outer skin from external factors.

Acid mantle is made up of sebum, lipids, sweat, and water to form a hydrolipidic film.

Acid mantle has a pH average of 5.5.
Acid Mantle

**Diagram:**
- **Endogenous Factors:**
  - Gender
  - Ethnicity
  - Body site
  - Sebum
  - Skin hydration
  - Sweat
  - Age
  - Diabetes

- **Skin pH**

- **Exogenous Factors:**
  - Skin microbiota
  - Climatic factors
  - Skin irritants
  - Skin care

**Factors Influencing Skin pH:**
- Epidermal barrier
- Buffer capacity
- Antimicrobial capacity

Transmission of pathogens by hands

Health-care workers: source, vector, or victim of MRSA?

*Volume 8, Issue 5*, May 2008, p.289-301
Health-care workers: source, vector, or victim of MRSA?

Werner C Albrich, Stephan Harbarth

There is ongoing controversy about the role of health-care workers in transmission of meticillin-resistant Staphylococcus aureus (MRSA). We did a search of the literature from January, 1980, to March, 2006, to determine the likelihood of MRSA colonisation and infection in health-care workers and to assess their role in MRSA transmission. In 127 investigations, the average MRSA carriage rate among 33,318 screened health-care workers was 4.6%; 5.1% had clinical infections. Risk factors included chronic skin diseases, poor hygiene practices, and having worked in countries with endemic MRSA. Both transiently and persistently colonised health-care workers were responsible for several MRSA clusters. Transmission from personnel to patients was likely in 63 (93%) of 68 studies that undertook genotyping. MRSA eradication was achieved in 449 (88%) of 510 health-care workers. Subclinical infections and colonisation of extranasal sites were associated with persistent carriage. We discuss advantages and disadvantages of screening and eradication policies for MRSA control and give recommendations for the management of colonised health-care workers in different settings.

Introduction

Hospitals worldwide are increasingly concerned by workers in MRSA transmission. 127 investigations, published in 120 articles, provided the number of
Chief Complaint Review

Recurrent MRSA Skin Infections in Atopic Dermatitis

Peck Y. Ong, MD a,b Los Angeles, Calif

Methicillin-resistant Staphylococcus aureus (MRSA) is a frequent cause of recurrent skin and soft tissue infections. For patients with atopic dermatitis, recurrent skin infections with MRSA often lead to eczema exacerbation. There is currently no standard practice in the prevention of recurrent MRSA soft tissue infections in the general and the atopic dermatitis populations. The current article reviews recent data on S aureus decolonization treatments for the prevention of recurrent MRSA soft tissue infections in the community setting. © 2014 American Academy of Allergy, Asthma & Immunology (J Allergy Clin Immunol Pract 2014;2:396-9)

Key words: Eczema; Community-associated MRSA; USA300; Skin and soft tissue infection; Decolonization; Household contact; Chlorhexidine; Hibiclens; Hypochlorite; Bleach; Clorox

Atopic dermatitis (AD) is a common chronic skin disease that is associated with elevated IgE, food and/or respiratory allergies, and recurrent skin infections. More than 90% of patients with AD are colonized with Staphylococcus aureus compared with only 10% in healthy individuals (reviewed in Ong and Leung1). S aureus infection is common in AD due to compromised skin barrier and with those isolated from a general population of AD patients with AD.4 Other potential mechanisms by which S aureus triggers AD include the production of α- and δ-toxins, which cause keratinocyte toxicity and mast cell activation, respectively.1,5

Community-associated (CA) MRSA skin and soft tissue infections (SSTI) have become a common reason for visits to outpatient clinics and emergency departments in the United States.6 These infections have mainly been associated with the emergence of MRSA clone USA300. For patients with AD, eczema exacerbation caused by MRSA SSTI has also become a significant clinical problem in recent years.7 The percentage of MRSA in patients with S aureus—colonized AD has been reported to range from 11% to 34%.8-11 Suh et al9 reported that 13% of all patients with AD are colonized with MRSA, this is significantly higher than the 1% to 3% of MRSA colonization reported in the general population.9 Lo et al10 also found that patients with AD and with MRSA colonization are more likely to develop SSTI than those with methicillin-sensitive S aureus colonization. AD constitutes a risk factor for colonization, recurrent infection, and transmission of MRSA.12-14 Infection with MRSA leads to a vicious cycle of AD flare and infection (Figure 1).15 It also has been observed that
Murphy’s Law

Anything that can go wrong will go wrong
Refillable soap dispensers

Do not add soap to a partially empty soap dispenser.

If soap dispensers are reused, follow recommended procedures for cleansing (IA).

Sinks/Plumbing
Faucet Aerators

Numerous outbreaks associated with faucet aerators.

Purpose of aerators:
- Conserve water while maintaining high pressure
- Saves $
- Reduce splashing

Replace or clean your faucet aerators, as they can become clogged with silt and biofilm.

The Impact of Aerator on Water Contamination by Emerging Gram-Negative Opportunists in At-Risk Hospital Departments. ICHE. Feb. 2014
Shallow sink bowl enables potentially contaminated water to splash onto patient care items, healthcare worker hands, and into patient care spaces more than four feet from the sink itself.

Sinks in the Future

Ozonated water
Laminar flow
Self flushing
Motion activated
Cleans without soap
Prevents bacterial growth and biofilm
Disinfects drain and trap
Integrates with hand hygiene monitoring programs
That sinking feeling: eradicating *Pseudomonas* and *Candida auris* from a sink drain system using ozonated water

Scott Livingston, BA1,2; Jennifer L. Cadnum, BS1; Annette L. Jencson BSMT, CIC1; Scott Gestrich, MD1; & Curtis J. Donskey, MD1,2

1 Research Service, Cleveland VA Medical Center, Cleveland, Ohio
2 Case Western Reserve University School of Medicine, Cleveland, Ohio

**Introduction**

- Contaminated sinks and drains are rapidly emerging as a cause of healthcare-associated infections, particularly in intensive care units (ICUs)
- Drain contamination is particularly difficult to eradicate due to the propensity for biofilm formation in piping
- We tested the benefit of introducing ozone into the water supply for decolonization of sinks and sink plumbing

**Methods**

- We evaluated the efficacy of ozonated water for reduction of methicillin-resistant *Staphylococcus aureus* (MRSA), *Pseudomonas* sp, and *Candida auris* on steel disks
- On steel disks, organisms were exposed to ozonated water with concentration ≈0.9 ppm for 10 minutes
- We also evaluated activity of ozonated water in a sink model deliberately colonized with *Pseudomonas* sp and *Candida auris*
- Ozonated water was added to the system via the faucet

**Results**

- On steel discs, MRSA, *Pseudomonas*, and *C. auris* were reduced by >3 log10 colony-forming units (CFUs) with 10 minutes of exposure to ozonated water
- In the sink model, we demonstrated total elimination of *C. auris* and *Pseudomonas* sp at the strainer within 2 days of ozone activity (figure 1, 2)
- We also demonstrated total elimination of both organisms at the trap within 9 days of ozone activity (figure 1, 2)
- Beyond the trap there was no significant decolonization (figure 1, 2)

**Conclusions and Acknowledgements**

- Our data suggest that ozonated water can effectively kill MRSA, *C. auris*, and *Pseudomonas* spp.
- An ozone generating sink can self-clean, reducing the burden of *C. auris* and *Pseudomonas*
- This device has the potential to reduce the number of sink-associated infections in hospitals, and merits further investigation
- Class 1 Inc. & FRANKE provided the testing apparatus and had no role in the design
Soap

Bland soap

. Available in various forms:
  ◦ bar soap
  ◦ liquid
  ◦ leaf

Occasionally, plain soaps have become contaminated

Chlorhexidine gluconate (CHG)

Has a strong persistent effect if not counteracted
Increased effectiveness with repeat applications
Incompatible with some non-ionic inorganic chemicals and some anions
Do not use near mucous membranes
Toxicity to ears and eyes reported
Do not use in open wounds
More effective for gram (+) organisms than gram (-)
Chloroxylenol - para-chloro-meta-xylenol (PCMX)

Halogen-substituted phenolic compound

Activity of chloroxylenol is apparently attributable to the inactivation of bacterial enzymes and alteration of cell walls

Relatively few articles dealing with the efficacy of chloroxylenol-containing preparations

Chloroxylenol is not as rapidly active as chlorhexidine gluconate or iodophors

Minimally affected by the presence of organic matter, but is neutralized by non-ionic surfactants
Iodine Based

Rapidly neutralized in presence of organic materials such as blood or sputum. Wide range of activity but requires sufficient contact time.

Residual effect is minimal if wiped off or rinsed.

The antimicrobial activity of iodophors also can be affected by pH, temperature, exposure time, concentration of total available iodine and the amount and type of organic and inorganic compounds present (e.g. alcohols and detergents).

Iodophor antiseptics have become contaminated with Gram-negative bacilli as a result of poor manufacturing processes.
Triclosan enters bacterial cells and affects the cytoplasmic membrane and synthesis of RNA, fatty acids, and proteins.

Has persistent activity on the skin. Its activity in hand-care products is affected by pH, the presence of surfactants or humectants, and the ionic nature of the formulation.

Most formulations containing less than 2% triclosan are well tolerated and seldom cause allergic reactions.
Large group of compounds:

• Alkyl benzalkonium chloride
• Benzethonium chloride,
• Cetrimide
• Cetylpyridium chloride
Hexachlorophene is a bisphenol composed of two phenolic groups and three chlorine moieties.

In the 1950s and early 1960s, emulsions containing 3% hexachlorophene were widely used for hygienic handwashing, as surgical scrubs, and for routine bathing of infants in hospital nurseries.

Infants bathed with hexachlorophene sometimes developed neurotoxicity (vacuolar degeneration).
When alcohol-based handrub is available in the health-care facility for hygienic hand antisepsis, the use of antimicrobial soap is not recommended (II).

Dose considerations for alcohol-based hand rubs

Wilkinson et al. address an important topic in a very systematic way. They found that in hygienic hand disinfection, an application time of alcohol-based hand rub (ABHR) of 20–30 s is considered acceptable among volunteers depending on the formulation, that it requires on average 1.5–2 mL to keep hands wet for this application time, and that the application of such a small volume usually fails to meet the EN1500 efficacy criteria. Based on their findings they propose an additional test using volumes and times that are acceptable to the user. Products that fulfil the requirements of EN1500 would be subjected to a further test using the same methodology but with the manufacturer’s recommended volume and time of application (not less than 30 s), with the test product compared with the reference alcohol applied in the same manner. This additional test would establish that a given product that passes EN1500 also performs at least as well as the reference alcohol when compared at realistic contact times and volumes. We do agree that realistic contact times are critical for a product that is provided at the point of care, only a few seconds away from the patient, but how realistic is the recommendation of a specific dose for an ABHR?

The proposal of Wilkinson et al. is to perform additional testing to show that a specific volume (e.g., 1.5 mL) of an ABHR that has passed the EN1500 testing is non-inferior to the application of the same volume of the reference alcohol of EN1500. We have two concerns in that respect:

1. The EN1500 efficacy test can be performed in many different ways as well as 2×3 mL in 30 s, 2×2 mL in 2×15 s, or 2×3 mL in 2×20 s. There is no restriction on volume as long as the application time is between 30 and 60 s. The additional testing for formulations which are not effective enough with 3 mL for 30 s would be possible and would place these formulations on the same level as more efficacious ABHRs as long as the additional testing reveals non-inferiority to the small volume of reference alcohol.

2. The practical implications of the additional data are not entirely clear. For example, if an ABHR fulfils the EN1500 efficacy requirement with 3 mL in 30 s and ‘fulfils’ the additional testing with 1.5 mL, what shall be the conclusion? Shall it be a general recommendation to use a volume of 1.5 mL on all hand sizes? Another example might be where an ABHR fails to fulfil the EN1500 efficacy requirement with 3 mL, but fulfilts it with 6 mL in 30 s. If it is then found to ‘fulfil’ the additional testing with 1.5 mL, what shall be the conclusion? Is the formulation now safe to be used with, for example, 1.5 mL after the additional testing?
Alcohol

Additives/Combo

Isopropyl alcohol appears to be more toxic than ethanol.

The efficacy of alcohol-based hand hygiene products is affected by a number of factors, including the type of alcohol used, the concentration of alcohol, the contact time, the volume of alcohol used, and whether the hands are wet when the alcohol is applied.
To clean or kill?

Use an alcohol-based handrub as the preferred means for routine hand antisepsis if hands are not visibly soiled. (IA)

If alcohol-based handrub is not obtainable, wash hands with soap and water (IB).

Before handling medication or preparing food perform hand hygiene using an alcohol-based handrub or wash hands with either plain or antimicrobial soap and water (IB).

Soap and alcohol-based handrub should not be used concomitantly (II)

WHO Guidelines on Hand Hygiene in Health Care
Brushes
Transmission of bacteria is more likely to occur from wet skin than from dry skin.

The hygienic efficacy of hand drying includes drying efficiency.

Paper towels are superior to electric air dryers.

Drying hands thoroughly with single-use, disposable paper towels is the preferred method of hand drying in health care.

PRACTICE FORUM

Pseudomonas aeruginosa outbreak in a neonatal intensive care unit: A possible link to contaminated hand lotion

Victoria E. Becks, RN, BSN
Nancy M. Lorenzoni, RN, CIC
Green Bay, Wisconsin

This article describes a prolonged outbreak of Pseudomonas aeruginosa. The attack rate of this outbreak was 8.5%, with no associated mortality. Hand lotion contaminated with P. aeruginosa was implicated in the transmission of organisms; removal of this hand lotion ended the outbreak. Contaminated hand lotion applied to clean hands of health care workers may have led to direct inoculation of infants at high risk for infection.

(AJIC AM J INFECT CONTROL 1995;23:396-8)
Compatibility

Glove Compatible

Mineral oil and petrolatum, common emollients in skin-care formulations, have been shown to contribute to latex glove deterioration.

Following the use of powdered gloves, some alcohol-based handrubs may interact with residual powder, resulting in a gritty feeling on hands.

CHG Compatible

Lotion

Alcohol hand rub
Can improving patient hand hygiene impact *Clostridium difficile* infection events at an academic medical center?

\(^f\)Division of Infectious Diseases and Department of Infection Control, UPMC Mercy Hospital, University of Pittsburgh, Pittsburgh, PA

**Background:** Hand hygiene plays an important role in the prevention of *Clostridium difficile* (CDI) infection (CDI). Patient hand hygiene (PHH) may be a potentially underused preventative measure for CDI. Patient mobility and acuity along with a lack of education present obstacles to PHH for the hospitalized patient. Surveys of patients at our institution showed a need for increased PHH opportunities. The objective of this study was to increase PHH and to examine if PHH affected CDI at our hospital.

**Methods:** A biphasic, quasi-experimental study was performed to increase PHH through education for staff and to provide education, assistance, and opportunities to the patient for hand cleaning. PHH practice was assessed by patient surveys and analyzed by \(\chi^2\) test. PHH impact on CDI was determined by following local healthcare facility-reported *Clostridium* laboratory-identified events data analyzed by National Healthcare Safety Network.
Revisiting the hand wipe versus gel rub debate: Is a higher-ethanol content hand wipe more effective than an ethanol gel rub?

Natalie N. D’Antonio, MS,a John D. Rihs, BS,a Janet E. Stout, PhD,b and Victor L. Yu, MDc
Pittsburgh, Pennsylvania

Background: The Centers for Disease Control and Prevention’s guidelines for hand hygiene state that the use of alcohol-based hand wipes is not an effective substitute for the use of an alcohol-based hand rub or handwashing with an antimicrobial soap and water. The objective of this study was to determine whether a hand wipe with higher ethanol content (65.9%) is as effective as an ethanol hand rub or antimicrobial soap in removing bacteria and spores from hands.

Methods: In two separate experiments, the hands of 7 subjects were inoculated with a suspension of Serratia marcescens or Geobacillus stearothermophilus. Subjects washed with each of 3 different products: 65.9% ethanol hand wipes (Sani-Hands ALC), 62% ethanol gel rub (Purell), and antimicrobial soap containing 0.75% triclosan (Kindred Kare).

Results: A total of 56 observations were analyzed for S marcescens removal and 70 observations were analyzed for G stearothermophilus removal. The rank order of product efficacy for both bacteria and spore removal was antibacterial soap > 65.9% ethanol hand wipes > 62% ethanol hand rub. Mean S marcescens log reductions (±SD) for the 65.9% ethanol alcohol wipe, 62% ethanol alcohol rub, and antimicrobial foam soap were 3.44 ± 0.847, 2.32 ± 1.065, and 4.44 ± 1.018, respectively (P < .001). Mean G stearothermophilus log reductions for the 65.9% ethanol wipe, 62% ethanol rub, and antimicrobial foam soap were 0.51 ± 0.26, −0.8 ± 0.32 increase over baseline, and 1.72 ± 0.62, respectively (P < .001).

Conclusion: The alcohol-based hand wipe containing 65.9% ethanol was significantly more effective than the 62% ethanol rub in reducing the number of viable bacteria and spores on the hands.

Key Words: Hand hygiene; waterless; hand sanitizer; alcohol; antimicrobial.

*Smoke compartment: A space within a building enclosed by smoke barriers on all sides, including the top and bottom.*

**Sources of ignition: Appliances or equipment that, because of their intended modes of use or operation, are capable of providing sufficient thermal energy to ignite flammable gas-air mixtures.** Examples include wall outlets, thermostats, and appliances.

CDC report calls attention to hand sanitizer risk in children

Hand sanitizers are everywhere. They are cheap, effective disinfectants, and many are easy to carry around. But lately, these products have been scrutinized for the potential harm they can have on children.

“Many caregivers are unaware of the very high alcohol content present in alcohol-based hand sanitizers, which can contain up to 60% to 95% alcohol,” said Cynthia Santos, MD, from CDC’s National Center for Environmental Health. “Young children may inadvertently consume these hand sanitizers because of their appealing scents, like apple, vanilla, and citrus.”

In a new report from CDC, researchers analyzed data reported to the National Poison Data System (NPDS) from 2011-14 on exposures to alcohol- and non-alcohol-based hand sanitizers in children who were 12 years old or younger. A total of 70,669 hand sanitizer exposures in this age group were reported to NPDS, including 65,293 (92%) alcohol-based exposures and 5,376 (8%) non-alcohol-based exposures. Adverse health effects were more likely to be reported for alcohol-based hand sanitizer exposures, and they tended to be worse than those for non-alcohol-based hand sanitizer exposures.

“Younger kids are more susceptible to adverse effects [from these products] because there is not as much glycogen in their liver,” said Greene Shepherd, PharmD, clinical professor at the University of North Carolina Eshelman School of Pharmacy.

The most common type of adverse health effect for both alcohol- and non-alcohol-based sanitizers—no NFPS reported calls about co-exposures to other agents were included in the analysis.

Most exposures—91%—occurred in children aged 5 years or younger. Children aged 6 to 12 years had more intentional exposures, a finding the report authors said could indicate that these products are being abused among older children.

Besides emphasizing the knowledge health care providers can pass along about safety precautions, the report authors took the opportunity to recommend washing hands with soap and water when available, which is currently the recommended method of hand hygiene in non-health-care settings. If soap and water are not available, use of a hand sanitizer that contains at least 60% alcohol is recommended, or a non-alcohol-based hand sanitizer or wipe can be used.

FDA made the same recommendation about using soap and water (in a non-health-care setting) in 2016 when it banned 19 active ingredients in antibacterial soaps and body washes, including triclosan and triclocarban—the two most commonly used ingredients.

Most exposures—91%—occurred in children aged 5 years or younger. Children aged 6 to 12 years had more intentional exposures, which could indicate that these products are being abused among older children.

In an article, Pharmacy Today published about the announcement, an FDA spokesperson said that emerging research showed that some antibacterial ingredients could pose health risks in people.

“Short-term animal studies suggest that triclosan can cause liver damage, disrupt hormones, and lead to birth defects,” the agency commented in its announcement. 

In the study, massive amounts of triclosan were fed to pregnant rats, and the researchers saw signs of liver damage. Triclosan can interfere with the hormones that regulate a woman’s menstrual cycle, and it disrupts the hormones needed for normal growth and development of the fetus.
Selection And Handling Of Hand Hygiene Agents

A. Provide HCWs with efficacious hand hygiene products that have low irritancy potential (IB)

B. To maximize acceptance of hand hygiene products by HCWs, solicit their input regarding the feel, fragrance, and skin tolerance of any products under consideration. In some settings, cost may be a primary factor (IB)

C. When selecting hand hygiene products: determine any known interaction between products used to clean hands, skin care products, and the types of gloves used in the institution (II) solicit information from manufacturers about the risk of contamination (IB); ensure that dispensers are accessible at the point of care (IB); ensure that dispensers function adequately and reliably and deliver an appropriate volume of the product (II); ensure that the dispenser system for alcohol-based formulations is approved for flammable materials (IC); solicit information from manufacturers regarding any effect that hand lotions, creams, or alcohol-based handrubs may have on the effects of antimicrobial soaps being used in the institution (IB).
Factors to be taken into consideration for product selection include:

- Nursing tasks – food prep, aseptic procedures,
- Resident use – before meals, bathing, sensitive skin
- Cost/contract
- Fragrance - less is more
- Consistency (consider plumbing, flooring, walls, etc.)

Lotion soap
Alcohol
- Gel
- Foam
- Solutions
Foam or Liquid Soap

Foam
- Use less product
- Spreads easier
- Easier to handle
- Easier to rinse off (10% less water)
- Easier to plumbing fixtures
Foam Soap Effectiveness

On a scale of 1-7, rate the current condition of the skin on your hands:

- Normal: no redness, blotching, or rash
- Completely intact. No abrasions or fissures
- Normal amount of moisture
- No itching, burning, or soreness

Please identify how often you used the following hand hygiene agents.

<table>
<thead>
<tr>
<th></th>

**Visual Scoring of Skin Scale**

Using a magnifying glass, visually inspect the skin on the dominant hand using the following scale:

Circle one number below:

<table>
<thead>
<tr>
<th>Number</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td><strong>Normal</strong> - No observable scale or irritation of any kind.</td>
</tr>
<tr>
<td>1</td>
<td><strong>Very slightly scaly</strong> – Occasional scale that is not necessarily uniformly distributed</td>
</tr>
<tr>
<td>2</td>
<td><strong>Slightly scaly</strong> – Scale in sulci and on plateaus. More visible scale that is more uniformly distributed, but no widespread uplifting.</td>
</tr>
<tr>
<td>3</td>
<td><strong>Scaly</strong> – Visible scale giving the overall appearance of the skin surface a whitish appearance. Definite uplifting of edges or scale-sections. Hand is rough to the touch.</td>
</tr>
<tr>
<td>4</td>
<td><strong>Scaly to Very Scaly</strong> – More scale and pronounced separation of scale edges from skin, although they may still be lying flat on the skin surface. Some evidence of cracking in sulci and plateaus. Also, skin may appear irritated with some reddening.</td>
</tr>
<tr>
<td>5</td>
<td><strong>Very scaly</strong> – Extensive cracking of skin surface. In some cases, scales are very large, but some individuals never develop large scales. The skin may appear to be very irritated, with widespread reddening and/or occasional bleeding.</td>
</tr>
</tbody>
</table>
**Hand Skin Assessment Form**

On a scale of 1-7 rate the current condition of the skin of your hands.
